

Electromagnetic optical cable

Overview

Fiber optic communication relies on transmitting information as pulses of light through thin strands of glass or plastic called optical fibers. Instead of using electrical signals (like in traditional copper wires), it uses electromagnetic radiation in the form of light. Uplink is realized generally by means of optical fiber. Optical fiber cables are usually buried or suspended nearby earth surface. Under influence of these fields the polarization plane of light. Fiber optic cables can carry vastly more data at higher speeds without the signal degradation commonly associated with copper wires. This capability results in enhanced performance in data-heavy applications, such as streaming services, online gaming, and enterprise-level operations. Rochester Cable designs and manufactures electro-optical cables that combine optical fibers and electrical conductors for harsh environments.
