

# How many joints are there between long-distance optical cables

## Overview

Fiber optic joints or terminations are made two ways: 1) splices which create a permanent joint between the two fibers or 2) connectors that mate two fibers to create a temporary joint and/or connect the fiber to a piece of network gear. Common connector types are named FC, SC and LC for single-mode applications and ST for multimode, but there are also dozens of other types, with special qualities such as duplex connections, particularly small size, built-in shutter for improved laser safety, etc. These connections are essential in fiber optic networks, enabling the extension, branching, or repair of fiber cables while ensuring minimal signal loss during transmission. Different techniques are used to interconnect fibers. Either joining method must have three primary characteristics. Many factors cause attenuation in fiber optic cables: inherent loss, bending, impurities, refractive index, butt joints, and so on. Intrinsic loss: Rayleigh scattering, inherent absorption.
